

**Each question worth 2 points**

**Strong ligands:**  $\text{CN}^- > \text{NO}_2^- > \text{en} > \text{NH}_3$      **Weak ligands:**  $\text{H}_2\text{O} > \text{OH}^- > \text{F}^- > \text{Cl}^- > \text{Br}^-$

**1.** In the coordination complex,  $[\text{Ag}(\text{NH}_3)_2]^+$ , the electrons binding the  $\text{Ag}^+$  to the  $\text{NH}_3$  come from  
 a) the  $\text{Ag}^+$  5s electrons     b) the  $\text{Ag}^+$  4d electrons  
 c) the  $\text{NH}_3$  2s electrons     **d) the  $\text{NH}_3$  lone pair electrons**  
 *$\text{Ag}^+$  has no valence (5s) electrons, so bonding electrons must come from ligand and comes from ligand lone pair.*

**2.** If a coordination complex has bidentate ligands and octahedral geometry, how many ligands does it have?  
 a) 1 ligand     b) 2 ligands     **c) 3 ligands**     d) 4 ligands     e) 6 ligands  
*bidentate means two bonds per ligand, octahedral means 6 bonds, so  $6/2 = 3$  bonds per ligand*

**3.** The complex  $[\text{Co}(\text{NO}_2)_6]^{4-}$  will have how many unpaired d electrons:  
 a) 0     **b) 1**     c) 2     d) 3     e) 4  
 *$\text{Co}^{2+}$  is a  $d^7$  metal.  $\text{NO}_2^-$  is a strong ligand leading to a low spin state with 6 paired off-axis d electrons and 1 unpaired on-axis d electron*

**4.** The coordination complex  $[\text{Ni}(\text{en})_3]^{2+}$  absorbs yellow light (at 560 nm). Calculate  $\Delta$  in kJ/mol.  
 Constants:  $h = \text{Planck's constant} = 6.63 \times 10^{-34} \text{ J}\cdot\text{s}$ ,  $c = \text{speed of light} = 3.00 \times 10^8 \text{ m/s}$  and  
 Avogadro's Number =  $6.02 \times 10^{23}$ .  
**a) 214 kJ/mol**     b) 0.214 kJ/mol     c) 21 kJ/mol     d) 83,113 kJ/mol  
 $E = hc/\lambda = (6.63 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})/(560 \times 10^{-9} \text{ m}) = 3.55 \times 10^{-19} \text{ J/complex}$   
 $E = (3.55 \times 10^{-19} \text{ J/complex})(6.02 \times 10^{23} \text{ complex/mol})(1 \text{ kJ}/1000 \text{ J}) = 214 \text{ kJ/mol}$

**5.** Which coordination compound will absorb light at the longest wavelength?  
 a)  $[\text{ZnCl}_4]^{2-}$      b)  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$      c)  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$      **d)  $[\text{FeBr}_6]^{4-}$**   
*last complex has weakest ligand and is  $\text{Fe}^{2+}$  (causes smaller gap than more highly charged  $\text{Fe}^{3+}$ )*
