## Part A: d-orbital Splitting in Coordination Compounds

**1.** For each of the following, sketch the d-orbital energy diagram and fill the diagram with d electrons. Determine the number of unpaired electrons, whether the complex is high-spin or low-spin, and label whether the complex is paramagnetic or diamagnetic.

1. [Ti(H<sub>2</sub>O)<sub>6</sub>]<sup>2+</sup>

2.  $[V(C_2O_4)_3]^{4-}$ 

3. [Mn(en)<sub>3</sub>]<sup>2+</sup>

4. [CoF<sub>6</sub>]<sup>3-</sup>

5. [Co(NH<sub>3</sub>)<sub>6</sub>]<sup>3+</sup>

6. [FeCl<sub>6</sub>]<sup>3-</sup>

The  $[FeCl_6]^{3-}$  ion is more paramagnetic than  $[Fe(CN)_6]^{3-}$ . Can you explain?

## Part B: Absorption of Light

**2.** Estimate the Crystal Field Splitting Energy ( $\Delta_0$ ) for a blue solution of  $[Cu(NH_3)_6]^{2^+}$ . The maximum

absorption wavelength ( $\lambda_{max}$ ) is 615nm.

Use  $\Delta_0 = E = hc/(\lambda_{max})$  where  $h = 6.62608 \times 10^{-34}$  J sec and  $c = 2.997925 \times 10^8$  m/sec

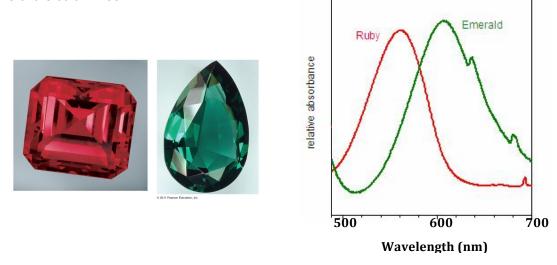

**3.** You made a sample containing  $Fe^{2+}$  and it is light blue-green.

a) Based on the color, do you expect the sample to be low-spin or high-spin?

b) What kind of experiment could you do to figure this out (hint: draw the di-orbital splitting diagram)

**4.** An aqueous solution of  $Ni^{2+}$  is green but  $Zn^{2+}$  is colorless. Draw the d-orbital diagrams and fill with d electrons. Once the diagrams are drawn, can you explain why  $Zn^{2+}$  is not colored?

**5.** Below are pictures of a ruby (red) and an emerald (green). A ruby is an aluminum oxide  $(Al_2O_3)$  and an emerald is a beryllium aluminosilicate  $(Be_3Al_2(SiO_3)_6)$ . Both contain trace amounts of  $Cr^{3+}$  ions, which is the reason the gems are colored. Using the visible spectra to the right, calculate the Crystal Field Splitting Energies  $(\Delta_0)$  for both the ruby and emerald. Which gem absorbs the lowest energy? Can you explain in terms of the color wheel?

Use  $\Delta_0 = E = hc/(\lambda_{max})$  where  $h = 6.62608 \times 10^{-34}$  J sec and  $c = 2.997925 \times 10^8$  m/sec

**6.** The complex ion  $[Co(CO_3)_3]^{3-}$  is an octahedral complex with bidentate carbonate ions as ligands. It has one absorption band in the visible region of the spectrum at 640nm.

- a) Predict the color of the complex.
- b) What is the energy associated with this wavelength of light?
- c) Based on your answer, is carbonate ion a weak or strong field ligand? Is the C or O bound to the Co<sup>3+</sup> ion?
- d) Is  $[Co(CO_3)_3]^3$  paramagnetic or diamagnetic?
