Camouflage: Winning at Hide and Seek

Organisms have evolved many different ways to avoid being detected and eaten by predators. One of these is called camouflage. Camouflage refers to when a prey organism attempts to blend in with the background. How does such a defense system work in a changing world? Snowshoe hares are large rabbits that life in the northern United States and Canada (Zimova et al. 2014). They are preyed upon by various species, particularly Canadian lynx (a large cat). To escape detection, snowshoe hares molt their fur color at the start of every winter from the brown color they have during summer, to a snowy white fur. The latter helps them blend in with a snowfilled environment. They then molt back to brown for the summer. Global climate change has caused the snow to arrive later in the fall and to disappear earlier in the spring than in the recent past, and so Zimova et al. (2014) wanted to know if this has affected when snowshoe hares change their coat color. For my term paper, I will examine this article plus two others on the topic of camouflage.
