## CHEM. 250 <br> Dixon Second Homework Problems - Solutions

## Ch. 4: 25

25. Calculate the pH of rainwater that is in equilibrium with air that has an $\mathrm{SO}_{2}$ concentration of 2 ppm .
$P_{\mathrm{SO}_{2}}=(1 \mathrm{~atm})\left(2 \times 10^{-6}\right)=2 \times 10^{-6} \mathrm{~atm}$
$\left[\mathrm{H}_{2} \mathrm{SO}_{3}\right]=K_{\mathrm{H}} \mathrm{P}_{\mathrm{SO} 2}=(1.0 \mathrm{M} / \mathrm{atm})\left(2 \times 10^{-6} \mathrm{~atm}\right)=2 \times 10^{-6} \mathrm{M}$
Reaction: $\quad \mathrm{H}_{2} \mathrm{SO}_{3} \leftrightarrow \mathrm{H}^{+}+\mathrm{HSO}_{3}^{-} \quad \mathrm{K}_{a l}=0.017$
Note: although we can not really use an ICE (initial change equilibrium) table because $\mathrm{SO}_{2}$ will not be depleted from the gas phase and $\mathrm{H}_{2} \mathrm{SO}_{3}$ will be constant, we can expect that $\left[\mathrm{H}^{+}\right]=\left[\mathrm{HSO}_{3}^{-}\right]$(assuming no other sources of $\mathrm{H}^{+}$)
$K_{a l}=0.017=\left[\mathrm{H}^{+}\right]\left[\mathrm{HSO}_{3}^{-}\right] /\left[\mathrm{H}_{2} \mathrm{SO}_{3}\right]=\left[\mathrm{H}^{+}\right]^{2} / 2 \times 10^{-6}$
$\left[\mathrm{H}^{+}\right]=\left[(0.017)\left(2 \times 10^{-6}\right)\right]^{0.5}=1.84 \times 10^{-4} \mathrm{M}$
$\boldsymbol{p H}=3.73$
Ch. 7: 3, 5, 6, 8, 10, 24, 25, 26, 35, 44
26. What percentage of the earth's water is seawater? About $97 \%$. List the four most concentrated metal ions present in seawater. Sodium, magnesium, calcium, and potassium. What is the approximate concentration (in ppm ) of dissolved solids in seawater? 35,000 ppm.
27. How much dissolved solids can each of the following contain?
a. Brackish water - between 1000 and $35,000 \mathrm{ppm}$
b. Freshwater - less than 1000 ppm
c. Drinking water - less than 500 ppm
28. What is the dominant cation in each of the following:
a. Seawater $-N a^{+}$
b. Hard water - There are actually two dominant ions: $\mathrm{Mg}^{2+}$ and $\mathrm{Ca}^{2+}$.
29. In which of the following steps of the hydrologic cycle is water purified?
a. Condensation - Not purified
b. Precipitation - Not purified
c. Evaporation - Purified
d. Transpiration - Purified
30. At what temperature does water reach its maximum density? $4^{\circ} \mathrm{C}$. What are the implications of this property for life in a pond? The surface layer can be colder than deeper layers, allowing ice to form on the surface without causing freezing throughout the whole pond.
31. Suppose that the concentration of the greenhouse gas $\mathrm{CO}_{2}$ continues to increase in our atmosphere until it reaches 500 ppm . What effect would this increase have on the pH of rainwater? How much would the pH increase or decrease?
The increase in $\mathrm{CO}_{2}$ could decrease the pH of rainwater (if other sources of acidity like $\mathrm{SO}_{2}$ and acidic aerosol particles are minimal).
With the $\mathrm{CO}_{2}$ mixing ratio $=380 \mathrm{ppm},\left[\mathrm{CO}_{2}(\mathrm{aq})\right]=K_{H} P_{\mathrm{CO} 2}=(0.0338 \mathrm{M} / \mathrm{atm})\left(3.8 \times 10^{-4}\right.$ $\mathrm{atm})=1.28 \times 10^{-5} \mathrm{M}$
Reaction: $\quad \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \quad \mathrm{H}^{+}+\mathrm{HCO}_{3}^{-} \quad \mathrm{K}_{a l}=4.45 \times 10^{-7}$
Note: although we can not really use an ICE (initial change equilibrium) table because $\mathrm{CO}_{2}$ will not be depleted from the gas phase and $\mathrm{CO}_{2}$ will be constant, we can expect that $\left[\mathrm{H}^{+}\right]=\left[\mathrm{HCO}_{3}^{-}\right]$(assuming no other sources of $\mathrm{H}^{+}$)
$K_{a l}=4.45 \times 10^{-7}=\left[\mathrm{H}^{+}\right]\left[\mathrm{HCO}_{3}^{-}\right] /\left[\mathrm{CO}_{2}\right]=\left[\mathrm{H}^{+}\right]^{2} / 1.28 \times 10^{-5}$
$\left[H^{+}\right]=\left[\left(4.45 \times 10^{-7}\right)\left(1.28 \times 10^{-5}\right)\right]^{0.5}=2.39 \times 10^{-6} \mathrm{M}$
pH $=5.62$
With $\mathrm{CO}_{2}$ mixing ratio $=500 \mathrm{ppm},\left[\mathrm{CO}_{2}(\mathrm{aq})\right]=1.69 \times 10^{-5} \mathrm{M}$, and $\boldsymbol{p H}=5.56$ (so a decrease of 0.06 units).
32. What is the predominant carbonate species in natural waters with a pH of a. Greater than 11

These problems can be solved by looking at the $p K_{a 1}$ and $p K_{a 2}$ for $\mathrm{CO}_{2}(a q)$, which are 6.35 and 10.33, respectively. Since $p H>11$ is also $>p K_{a 2}$, the dominant species will be $\mathrm{CO}_{3}{ }^{2-}$.
b. Less than 5
$p H<p K_{a l}$, so $\mathrm{CO}_{2}(a q)$ is dominant species
c. Equal to 6.35

At $\mathrm{pH}=\mathrm{pK} \mathrm{Kal}_{1}, \mathrm{CO}_{2}(\mathrm{aq})$ and $\mathrm{HCO}_{3}^{-}$are present at equal concentrations.
d. Equal to 10.33

At $p H=p K_{a 2}, \mathrm{CO}_{3}{ }^{2-}$ and $\mathrm{HCO}_{3}^{-}$are present at equal concentrations.
26. Air is $21 \%$ oxygen. Calculate the molar concentration of dissolved oxygen in lake water than is saturated with air. What is this concentration in ppm? The Henry's law constant for oxygen is $1.28 \times 10^{-3} \mathrm{M} / \mathrm{atm}$.
$\left[O_{2}(\mathrm{aq})\right]=(0.21 \mathrm{~atm})\left(1.28 \times 10^{-3} \mathrm{M} / \mathrm{atm}\right)=2.69 \times 10^{-4} \mathrm{M}$. Assuming sea-level lake. ppm $\mathrm{O}_{2}(\mathrm{aq})($ by mass $)=\left(2.69 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\right)(32.00 \mathrm{~g} / \mathrm{mol})(1000 \mathrm{mg} / \mathrm{g})(1 \mathrm{ppm} / \mathrm{mg} / \mathrm{L})$ ppm $\mathrm{O}_{2}(\mathrm{aq})$ (by mass) $=\mathbf{8 . 6 0} \mathbf{p p m}$.
This is somewhat different than the answer in the textbook because I have assumed that $\%$ oxygen is for the actual atmosphere (rather than for dry air) or that the air in equilibrium with the lake is totally dry rather than saturated with water. The actual answer is probably half way between the two values (e.g. 8.45 ppm ) because a typical relative humidity will be around $50 \%$.
35. What is the main cause of acid mine damage? Give an equation to show how this acid is formed.
Acid mine damage is mainly caused by release of sulfuric acid which is formed from sulfides such as pyrite $\left(\mathrm{FeS}_{2}\right)$ that oxidize to sulfuric acid.
$2 \mathrm{FeS}_{2}+7 \mathrm{O}_{2}+2 \mathrm{H}_{2} \mathrm{O} \rightarrow 2 \mathrm{Fe}^{2+}+4 \mathrm{SO}_{4}{ }^{2-}+4 \mathrm{H}^{+}$
44. San Diego, California, draws its water supply from the Colorado River, which is several hundred miles away. The water flows in open aqueductes from the river to the city. Would you expect this to have any affect on the quality of the water?
Yes. As water evaporates, the dissolved solids (and concentrations of any low volatility trace species) will increase.
